Main decommissioning work and steps

Fuel removal from the spent fuel pool was completed in December 2014 at Unit 4 and started from April 15, 2019 at Unit 3. Dust concentration in the surrounding environment is being monitored and work is being implemented with safety first. Work continues sequentially toward the start of fuel removal from Units 1 and 2 and debris retrieval from Units 1-3.

Contaminated water management proceeds with the following three efforts:

1. **Efforts to promote contaminated water management based on the three basic policies**
   - 1. "Remove" the source of water contamination
   - 2. "Redirect" fresh water from contaminated areas
   - 3. "Retain" contaminated water from leakage

2. **Efforts to complete contaminated water treatment**
   - 4. Treatment of contaminated water in buildings
   - 5. Measures to remove α-nuclide and reduce the concentration in contaminated water
   - 6. Measures to alleviate the radiation dose of Zeolite sandbags in the Process Main Building and High-Temperature Incinerator Building and examine safe management methods

3. **Efforts to stably operate contaminated water management**
   - 7. Planning and implementing necessary measures to prepare for large-scale disasters such as tsunami and heavy rain
   - 8. Periodically inspecting and updating facilities to maintain the effect of contaminated water management going forward
   - 9. Examining additional measures as required, with efforts to gradually expand the scale of fuel debris retrieval
**Progress status**

- The temperatures of the Reactor Pressure Vessel (RPV) and Primary Containment Vessel (PCV) of Units 1-3 have been maintained within the range of approx. 20-40°C over the past month. There was no significant change in the concentration of radioactive materials newly released from Reactor Buildings into the air. It was concluded that the comprehensive cold shutdown condition had been maintained.

1. The values varied somewhat, depending on the unit and location of the thermometer.
2. In July 2020, the radiation exposure dose due to the release of radioactive materials from the Unit 1-4 Reactor Buildings was evaluated at less than 0.00005 mSv/year at the site boundary. The annual radiation dose from natural radiation is approx. 2.1 mSv/year (average in Japan).

**Toward installation of support to the Unit 1 FHM**

Before removing the fallen roof on the south side and other objects, to minimize the risk of the overhead crane/fuel-handling machine shifting, becoming imbalanced and subsequently falling, materials to support the fuel-handling machine (FHM) from below will be installed. For the FHM, preparation will start from September and the installation will be completed within October.

**Cutting of obstacles inside the PCV toward insertion of a robot to investigate inside Unit 1**

As part of efforts to investigate inside the Unit 1 Primary Containment Vessel (PCV), work to cut obstacles inside the PCV on the route for the investigation equipment started from May 26. For the defect of the abrasive supply part having occurred on July 7, the nozzle unit was replaced and the lack of any abnormality was confirmed. Work resumed from August 2 and cutting of the grating was completed on August 25. Cutting of obstacles will continue.

**Test to suspend water injection into the Unit 2 reactor (flash report)**

For Unit 2, a test to suspend water injection for about eight hours was conducted in FY2019 to optimize the emergency response procedures. A test to suspend water injection was also conducted for longer (period: August 17-20 (about 74 hours)) to verify the reproducibility of the temperature evaluation model while suspending water injection to the reactor and examine how best to inject water in future.

During the suspension period, temperatures at the RPV bottom and PCV increased by about 11.5 and 0.5°C respectively, showing variation almost within the assumed range.

**Ongoing Unit 3 fuel removal proceeding steadily**

Since the resumption on May 26, the fuel removal has progressed steadily and 315 of 566 fuel assemblies were removed. At the same time, rubble removal also proceeded steadily. On August 24, a lifting test was conducted for one fuel assembly with a deformed handle, which was excluded from the previous lifting test in May, and one fuel assembly, with which a deformed handle was detected after the previous lifting test. Based on the test results, it was confirmed that both fuel assemblies could be lifted.

**Treatment completion of temporarily stored Sr-treated water**

Treatment of Sr-treated water temporarily stored while awaiting treatment of multi-nuclide removal equipment and other facilities was completed on August 8, except for operation tanks necessary to treat the contaminated water generated daily. Following the completed treatment of Sr-treated water, performance verification of secondary treatment will commence from September 2020 for water treated by the multi-nuclide removal equipment or other facilities and its sum of concentration ratios required by law*, except for tritium, is 100 or more (approx. 2,000 m³). The performance verification will involve checking that the sum of concentration ratios required by law, except for tritium, is reduced to less than 1 following treatment by multi-nuclide removal equipment or other facilities. The procedures and process of nuclide analysis and others will also be reconfirmed.

* The sum of concentration ratios calculated to the concentration limits required by law as specified for each radioactive material.
Data of Monitoring Posts (MP1-MP8.)

Data (10-minute values) of Monitoring Posts (MPs) measuring the airborne radiation rate around site boundaries showed 0.385 – 1.249 μSv/h (August 1 - 25, 2020).

We improved the measurement conditions of monitoring posts 2 to 8 to measure the air-dose rate precisely. Construction work, such as tree-clearing, surface soil removal and shield wall setting, were implemented from February 10 to April 18, 2012. Therefore, monitoring results at these points are lower than elsewhere in the power plant site. The radiation shielding panels around monitoring post No. 6, which is one of the instruments used to measure the radiation dose at the power station site boundary, were taken off from July 10 - 11, 2013, since further deforestation, etc. had caused the surrounding radiation dose to decline significantly.
I. Confirmation of the reactor conditions

1. Temperatures inside the reactors

Through continuous reactor cooling by water injection, the temperatures of the Reactor Pressure Vessel (RPV) bottom and the Primary Containment Vessel (PCV) gas phase were maintained within the range of approx. 20 to 40°C for the past month, though it varied depending on the unit and location of the thermometer.

- Operation of the groundwater bypass

- Pumps are inspected and cleaned as required based on their operational status.

- Operation of the Water Treatment Facility special for Subdrain & Groundwater drains

- To reduce the level of groundwater flowing into the buildings, work began to pump up groundwater from wells (subdrains) around the buildings on September 3, 2015. The pumped-up groundwater was then purified at dedicated facilities and released from September 14, 2015, in the presence of officials from the Intergovernmental Liaison Office for the Decommissioning and Contaminated Water Issue of the Cabinet Office. Up until August 26, 2020, a total of 961,702 m³ had been drained after TEPCO and a third-party organization had confirmed that its quality met operational targets.

- As one of the multi-layered contaminated-water management measures, in addition to a waterproof pavement that
aims to prevent rainwater infiltrating, facilities to enhance the subdrain treatment system were installed and went into operation from April 2016, increasing the treatment capacity from 900 to 1,500 m³/day and improving reliability. Operational efficiency was also improved to treat up to 2,000 m³/day for almost one week during the peak period.

- To maintain the groundwater level, work to install additional subdrain pits and recover those existing is underway. The additional pits are scheduled to start operation sequentially, from pits for which work is completed (12 of 14 new subdrain pits went into operation). To recover existing pits, work for all three pits scheduled was completed and all went into operation from December 26, 2018. Work to recover another pit started from November 2019 (No. 49 pit).
- To eliminate the need to suspend water pumping while cleaning the subdrain transfer pipe, the pipe will be duplicated. Installation of the pipe and ancillary facilities was completed.
- Since the subdrains went into operation, the inflow to buildings tended to decline to under 150 m³/day when the subdrain water level declined below T.P. 3.0 m but increased during rainfall.

**Operation of multi-nuclide removal equipment**

- Regarding the multi-nuclide removal equipment (existing and high-performance), hot tests using radioactive water are underway (for existing equipment, System A: from March 30, 2013, System B: from June 13, 2013, System C: from September 27, 2013; and for high-performance equipment, from October 18, 2014). The additional multi-nuclide removal equipment went into full-scale operation from October 16, 2017.
- As of August 20, 2020, the volumes treated by existing, additional and high-performance multi-nuclide removal equipment were approx. 454,000, 678,000 and 103,000 m³, respectively (including approx. 9,500 m³ stored in the J1(D) tank, which contained water with highly concentrated radioactive materials at the System B outlet of the existing multi-nuclide removal equipment).
- To reduce the risks of strontium-treated water, treatment using existing, additional, and high-performance multi-nuclide removal equipment has been underway (existing: from December 4, 2015; additional: from May 27, 2015; high-performance: from April 15, 2015). Up until August 20, 2020, approx. 756,000 m³ had been treated.
- Toward reducing the risk of contaminated water stored in tanks
  - Treatment measures comprising the removal of strontium by cesium-absorption apparatus (KURION) (from January 6, 2015), the secondary cesium-absorption apparatus (SARRY) (from December 26, 2014) and the third cesium-absorption apparatus (SARRY II) (from July 12, 2019) are underway. Up until August 20, 2020, approx. 602,000 m³ had been treated.

**Measures in the Tank Area**

- Rainwater accumulates and is collected inside the area of contaminated-water tanks. After removing radionuclides, the rainwater is sprinkled on the ground of the site, if the radioactivity level does not meet the standard for discharging into the environment since May 21, 2014 (as of August 25, 2020, a total of 162,922 m³).
**Completion of mega float grounding to reduce the tsunami risk**

- To reduce the risk of floating due to tsunamis, work is being implemented to transfer the mega float to the inside of the Unit 1-4 open channel and utilize it as a bank.
- Filling mortar into the mega float started from April and its grounding was completed on August 3. This work reduced the risk of floating due to tsunamis.

**Treatment completion of temporarily stored Sr-treated water**

- Treatment of Sr-treated water temporarily stored while awaiting treatment of multi-nuclide removal equipment and other facilities was completed on August 8, except for operation tanks necessary to treat contaminated water generated daily.
- Following the completed treatment of Sr-treated water, performance verification of secondary treatment will commence from September 2020 for water treated by the multi-nuclide removal equipment or other facilities and its sum of concentration ratios required by law, except for tritium, is 100 or more (approx. 2000 m$^3$). The performance verification will involve checking that the sum of concentration ratios, excluding tritium, is reduced to less than 1 following treatment by the multi-nuclide removal equipment or other facilities. The procedures and process of nuclide analysis and others will also be reconfirmed.

---

### Figure 4: Status of contaminated water storage

- **Update on the storage amount by the sum of concentration ratios required by law in water treated by the multi-nuclide removal equipment or other facilities**
  - For the storage amount by the sum of concentration ratios required by law in water treated by the multi-nuclide removal equipment or other facilities, the ratios of the legally required concentrations are evaluated based on the results of sampling at the outlets of multi-nuclide removal equipment or other facilities. The ratios are then disclosed together with the storage amount on the contaminated water portal site of the website of the Tokyo Electric Power Company Holdings, Inc.
  - When the portal site is next updated (at the end of August), those of the tanks filled during April–June will be reflected in the storage amount by the sum of concentration ratios required by law. However, these filled tanks include reused tanks, in which radioactive materials in sludge or other substances still remained after washing for reuse. It was confirmed that due to the influence of these radioactive materials, the sum of concentration ratios required by law increased after receiving water treated by the multi-nuclide removal equipment or other facilities.
  - Accordingly, for reused tanks, there is a considerable difference between the sum of concentration ratios required by law evaluated by water at the outlets of the multi-nuclide removal equipment or other facilities and those based on sampling results of tanks. Taking these conditions into consideration, reused tanks will be indicated in a separate column from other tanks.
  - In addition, the contribution of Carbon-14, a factor of difference between the measurement values of total β and major nuclides which was reported in the Commission on Supervision and Evaluation of the Specified Nuclear Facilities, will also be reflected in the storage amount by the sum of concentration ratios required by law when the contaminated water portal site is updated the next time (at the end of August).

---

**2. Fuel removal from the spent fuel pools**

- Work to help remove spent fuel from the pool is progressing steadily while ensuring seismic capacity and safety. The removal of spent fuel from the Unit 4 pool commenced on November 18, 2013 and was completed by December 22, 2014.

---

**Main work to help spent fuel removal at Unit 1**

- From March 18, 2019, the removal of small rubble in the east-side area around the spent fuel pool (SFP) started using pliers and suction equipment, while small rubble removal on the south side of the SFP started from July 9.
- The well plug, which was considered misaligned from the normal position due to the influence of the hydrogen explosion at the time of the accident, was investigated for the period July 17 – August 26, 2019, by taking photos with a camera, measuring the air dose rate and collecting 3D images.
- A prior investigation on September 27, 2019 confirmed the lack of any obstacle which may affect the plan to install the cover over the SFP, the absence of any heavy object such as a concrete block, as detected in Unit 3 and the fact that panel- and bar-shaped rubble pieces were scattered on the rack.
- After examining two methods: (i) installing a cover after rubble removal and (ii) initially installing a large cover over the Reactor Building and then removing rubble inside the cover, method (ii) was selected to ensure safer and more secure removal.
- Before removing the fallen roof on the south side and other objects, to minimize the risk of the overhead crane/fuel-handling machine shifting, becoming imbalanced and subsequently failing, materials to support the fuel-handling machine from below will be installed. For the installation, preparation will start from September and the work will be completed within October.
- Rubble removal and other work will proceed steadily with safety first, toward starting fuel removal during the period FY2027 to FY2028.

**Main work to help spent fuel removal at Unit 2**

- On November 6, 2018, before investigating with a work plan to dismantle the Reactor Building rooftop and other tasks in mind, work to move and contain the remaining objects on the operating floor (1st round) was completed.
- On February 1, 2019, an investigation to measure the radiation dose on the floor, walls and ceiling inside the operating floor and confirm the contamination status was completed. After analyzing the investigative results, the "contamination concentration distribution" throughout the entire operating floor was obtained, based on which the air dose rate inside the operating floor could be evaluated. A shielding design and measures to prevent radioactive material scattering will be examined.
- From April 8, 2019, work to move and contain the remaining objects on the operating floor (second round) started.
such as materials and equipment which may hinder installation of the fuel-handling facility and other work. The second round mainly included moving the remaining small objects and placing them in the container. It also included cleaning the floor to suppress dust scattering and was completed on August 21.

- From September 10, 2019, work got underway to move and contain the remaining objects on the operating floor (third round), such as materials and equipment which may hinder the installation of the fuel-handling facility and other work. The third round mainly included moving the remaining large objects and placing them in the container.

- After completing the training to practice work skills for transportation, preparatory work inside the operating floor started from July 20, 2020. Containers housing the remaining objects during the previous work will be transported to the solid waste storage facility from August 26.

- For fuel removal methods, based on the investigative results inside the operating floor from November 2018 to February 2019, a method to access from a small opening installed on the south side of the building was selected with aspects such as dust management and lower work exposure in mind (the method previously examined had involved fully dismantling the upper part of the building).

- Main process to help fuel removal at Unit 3

  - From April 15, 2019, work got underway to remove 514 spent fuel assemblies and 52 non-irradiated fuel assemblies (566 in total) stored in the spent fuel pool. Seven non-irradiated fuel assemblies were then loaded into the transportation cask and transported to the common pool on April 23. The first fuel removal was completed on April 25.
  
  - The periodical inspection of the fuel-handling facility, which started on July 24, 2019, was completed on September 2, 2019. Some defective rotations of the tensile truss and mast were detected during the following adjustment work toward resumption of the fuel removal. In response, parts were replaced and the operation checked to confirm no problem.

- Fuel removal work was resumed from December 23, 2019 and has proceeded as planned.

- By February 14, 2020, a visual check of all fuel handles was completed.

- The inspection of the fuel-handling machine and other equipment and additional training for added workers, which had been conducted since March 30, 2020, were completed without issue by May 23, whereupon fuel removal resumed from May 26. At present, 315 of 566 fuel assemblies have been removed. Removal work has progressed steadily with 25 assemblies remaining, for which rubble needs to be removed from the fuel top.

- At the same time, rubble removal also proceeded steadily. On August 24, a lifting test was conducted for one fuel assembly with a deformed handle, which was excluded from the previous lifting test in May, and one fuel assembly, with which a deformed handle was detected after the previous lifting test. Based on the test results it was confirmed that both fuel assemblies could be lifted.

- Fuel removal continues and matters confirmed during rubble removal and the issue related to the handling of fuel assemblies with deformed handles will be addressed according to a plan to complete fuel removal by the end of FY2020.

3. Retrieval of fuel debris

- Status of obstacle cutting work related to the Unit 1 PCV inside investigation

  - As part of efforts to investigate inside the Unit 1 Primary Containment Vessel (PCV), work to cut obstacles inside the PCV on the route for the investigation equipment started from May 26.

  - For the defect of the abrasive supply part having occurred on July 7, the nozzle unit was replaced, and the lack of any abnormality was confirmed. Work was resumed from August 2 and cutting of the grating was completed on August 25. Cutting of obstacles will continue.

- Status of water sampling from the Unit 3 suppression chamber

  - To reduce the water level in the Unit 3 PCV in a phased manner, water sampling inside the suppression chamber started on July 21 to determine the water quality. To reduce exposure during the work, any dose increase around the sampling equipment was suppressed and the water was sampled several times from late July.

- Based on the sampling results obtained to date that showed relatively high concentration from the initial stage, the water quality is assumed to be similar to that of water in the suppression chamber targeted for this analysis. Work will continue taking the reduction of exposure dose into consideration and water sampling, analysis and water release will be completed within September based on future dose measurement and analytical results.

4. Plans to store, process and dispose of solid waste and decommission of reactor facilities

- Promoting efforts to reduce and store waste generated appropriately and R&D to facilitate adequate and safe storage, processing and disposal of radioactive waste

  - Management status of the rubble and trimmed trees

    - As of the end of July 2020, the total storage volume for concrete and metal rubble was approx. 297,700 m³ (+1,600 m³ compared to at the end of June with an area-occupation rate of 72%). The total storage volume of trimmed trees was approx. 134,400 m³ (slight increase, with an area-occupation rate of 77%). The total storage volume of used protective clothing was approx. 35,800 m³ (-2,000 m³, with an area-occupation rate of 52%). The increase in rubble was mainly attributable to rubble removal around the Unit 1-4 buildings and transfer of general waste and area arrangement within the site, while the decrease in used protective clothing was attributable to the incinerator operation.

  - Management status of secondary waste from water treatment

    - As of August 6, 2020, the total storage volume of waste sludge was 421 m³ (area-occupation rate: 60%), while that of concentrated fluid waste was 9,380 m³ (area-occupation rate: 91%). The total number of stored spent vessels, High-Integrity Containers (HICs) for multi-nuclide removal equipment and other vessels, was 4,886 (area-occupation rate: 77%).

5. Reactor cooling

The cold shutdown condition will be maintained by cooling the reactor by water injection and measures to complement the status monitoring will continue

- Ventilation check of the Unit 2 Reactor Pressure Vessel nitrogen injection line

  - The Unit 2 Reactor Pressure Vessel (RPV) nitrogen injection point is a single configuration. To improve the reliability of the Unit 2 nitrogen injection line, there are plans to install an additional line.

  - To select an additional line taking the ventilation, maintainability and other related factors of nitrogen injection into consideration, the ventilation of four candidate lines for the new injection point will be checked from August 31 to September 4.

  - This check will include nitrogen injection from each new candidate injection point to examine (1) the pressure increase rate of the Primary Containment Vessel (PCV), (2) ventilation conditions and (3) the maximum injection capacity.

  - The ventilation check can be conducted while leaving the existing RPV nitrogen injection line and the exhaust rate of the existing PCV gas control system unchanged.

- Results of the test to suspend water injection into Unit 2 reactors (flash report)

  - For Unit 2, a test to suspend water injection for about eight hours was conducted in FY2019 to optimize the emergency response procedures.

  - A test to suspend water injection was also conducted for a longer period (period: August 17-20 (about 74 hours)) to verify the reproducibility of the temperature evaluation model while suspending water injection to the reactor and examine how best to inject water in future.

  - During the suspension period, temperatures at the RPV bottom and PCV increased by about 11.5 and 0.5°C respectively, showing variation almost within the assumed range.

6. Reduction in radiation dose and mitigation of contamination

Effective dose-reduction at site boundaries and purification of port water to mitigate the impact of radiation on the external environment
Status of groundwater and seawater on the east side of Turbine Building Units 1-4

- In the Unit 1 intake north side area, the H-3 concentration was below the legal discharge limit of 60,000 Bq/L at all observation holes and remained constant or had been declining. The concentration of total β radioactive materials had remained constant overall but increased temporarily from April. The trend will continue to be monitored.
- In the area between the Unit 1 and 2 intakes, the H-3 concentration has been below the legal discharge limit of 60,000 Bq/L at all observation holes. It increased temporarily at No. 1-14 but is currently declining and remained constant or been declining at many observation holes overall. The concentration of total β radioactive materials has remained constant at many observation holes overall, though temporarily increasing at No. 1-11.
- In the area between the Unit 2 and 3 intakes, the H-3 concentration has been below the legal discharge limit of 60,000 Bq/L at all observation holes and remained almost constant or been declining, though it has been increasing or decreasing at No. 2-3. The concentration of total β radioactive materials has been increasing at No. 2-3 located on the east side of No. 2-5 at the highest location.
- In the area between Unit 3 and 4 intakes, the H-3 concentration has been below the legal discharge limit of 60,000 Bq/L at all observation holes and remained constant or been declining overall, though it increased at No. 3-4 in June but was lower compared to No. 3-3.
- The concentration of radioactive materials in drainage channels has remained constant, despite increasing during rainfall.
  - In the Units 1-4 open channel area of seawater intake for Units 1 to 4, the concentration of radionuclides in seawater has remained below the legal discharge limit, despite increases in Cs-137 and Sr-90 noted during rainfall. They have also been declining following the completed installation and the connection of steel pipe sheet piles for the sea-side impermeable walls. The concentration of Cs-137 has remained slightly higher in front of the south side impermeable walls and slightly lower on the north side of the east breakwater since March 20, 2019, when the silt fence was transferred to the center of the open channel due to mega float-related construction.
  - In the port area, the concentration of radionuclides in seawater has remained below the legal discharge limit, despite increases in Cs-137 and Sr-90 observed during rainfall. They have remained below the level of those in the Units 1-4 intake open channel area and been declining following the completed installation and connection of steel pipe sheet piles for the sea-side impermeable walls.
  - In the area outside the port, regarding the concentration of radioactive materials in seawater, those of Cs-137 and Sr-90 declined and remained low after steel pipe sheet piles for the sea-side impermeable walls were installed and connected.

7. Outlook of the number of staff required and efforts to improve the labor environment and conditions

Adequate number of staff will be secured in the long-term, while firmly implementing radiation control of workers. The work environment and labor conditions will be continuously improved by responding to the needs on the site.

Staff management

- The monthly average total of personnel registered for at least one day per month to work on site during the past quarter from April to June 2020 was approx. 8,900 (TEPCO and partner company workers), which exceeded the monthly average number of actual workers (approx. 6,300). Accordingly, sufficient personnel are registered to work on site.
- It was confirmed with the prime contractors that the estimated manpower necessary for the work in September 2020 (approx. 4,000 per day: TEPCO and partner company workers) would be secured at present. The average numbers of workers per day per month (actual values) were maintained, with approx. 3,400 to 4,400 since FY2018 (see Figure 7).
The number of workers from both within and from outside Fukushima Prefecture remained constant. The local employment ratio (TEPCO and partner company workers) as of July 2020 also remained constant at around 65%.

The monthly average exposure doses of workers remained at approx. 0.22, 0.20 and 0.21 mSv/month during FY2017, FY2018 and FY2019, respectively. (Reference: Annual average exposure dose 20 mSv/year ≈ 1.7 mSv/month)

For most workers, the exposure dose was sufficiently within the limit and allowed them to continue engaging in radiation work.

- Request for cooperation to the survey to improve the work environment
  - With the aim of improving the work environment for workers at the power station, an annual survey is being conducted. Distribution of the 11th survey questionnaire sheet will start sequentially from August 27, 2020.
  - The answers will be collected by the end of September 2020 and the results will be compiled in December 2020.
  - This survey includes a new question related to the COVID-19 infectious disease prevention countermeasures for the rest house. In addition, questions related to the usability of the emergency room (ER) are changed to those asking about the awareness of ER and whether or not the workers will use the ER.

- Status of heat stroke cases
  - Measures to further prevent heat stroke commenced from April 2020 to cope with the hottest season.

- In FY2020, four workers suffered heat stroke due to work up until August 24 (in FY2019, eight workers up until the end of August). Continued measures will be taken to prevent heat stroke.

COVID-19 infectious disease prevention countermeasures at the Fukushima Daiichi NPS

- At the Fukushima Daiichi Nuclear Power Station (NPS), countermeasures continue to be implemented according to the local infection status to prevent the COVID-19 infection spreading, such as requiring employees to take their temperature prior to coming to the office, wear masks at all times and avoid the “Three Cs” (Closed spaces, Crowded places, Close-contact settings) by shift-use of the rest house, etc.

- As of August 25, 2020, no TEPCO HD employees or cooperative firm laborers of the Fukushima Daiichi NPS had contracted COVID-19 and no significant influence on decommissioning work, such as a delay to the work processes, was identified.
### Status of seawater monitoring within the port (comparison between the highest values in 2013 and the latest values)

“The highest value” → “the latest value (sampled during August 17-24)”; unit (Bq/L); ND represents a value below the detection limit

Summary of TEPCO data as of August 25, 2020

The image is a site layout map of the TEPCO Holdings Fukushima Daiichi Nuclear Power Station. The map includes various facilities and storage areas, such as:

- **Rubble storage area**
- **Rubble storage area (planned)**
- **Trimmed trees area**
- **Mid-/low-level contaminated water tank (existing)**
- **Mid-/low-level contaminated water tank (planned)**
- **Secondary waste from water treatment (existing)**
- **Secondary waste from water treatment (planned)**
- **Waste treatment facility**
- **Non-controlled facility**
- **Analysis and research facility**

The map also highlights specific areas such as:

- **Futaba town**
- **Town boundary**
- **Rubble (covered by sheet)**
- **Rubble (container storage)**
- **Temporary trimmed trees storage pool**
- **Temporary waste sludge storage**
- **Spent adsorption vessel temporary storage facility**

The map is provided by Japan Space Imaging, with the photo taken on June 14, 2018.
Progress toward decommissioning: Fuel removal from the spent fuel pool (SFP)

Immediate target
Commence fuel removal from the Unit 1-3 Spent Fuel Pools

Unit 1
Toward fuel removal from the Unit 1 spent fuel pool, investigations have been implemented to ascertain the conditions of the fallen roof on the south side and the contamination of the well plug. Based on the results of these investigations, "the method to initially install a large cover over the Reactor Building and then remove rubble inside the cover" was selected to ensure a safer and more secure removal. Work continues to complete installation of a large cover by around FY2023 and start fuel removal from FY2027 to FY2028.

<Reference> Progress to date
Toward fuel removal from the Unit 1 spent fuel pool, investigations have been implemented to ascertain the conditions of the fallen roof on the south side and the contamination of the well plug. Based on the results of these investigations, "the method to initially install a large cover over the Reactor Building and then remove rubble inside the cover" was selected to ensure a safer and more secure removal. Work continues to complete installation of a large cover by around FY2023 and start fuel removal from FY2027 to FY2028.

Unit 2
Toward fuel removal from the Unit 2 spent fuel pool, based on findings from internal operating floor investigations from November 2018 to February 2019, instead of fully dismantling the upper part of the building, the decision was made to install a small opening on the south side and use a boom crane. Examination continues to start fuel removal from FY2024 to FY2026.

<Reference> Progress to date
Previously, potential to recover the existing overhead crane and the fuel handling machine was examined. However, the high radiation dose inside the operating floor meant the decision was taken to dismantle the upper part of the building in November 2015. Findings from internal investigations of the operating floor from November 2018 to February 2019 underlined the potential to conduct limited work there and the means of accessing from the south side had been examined.

Unit 3
Prior to the installation of a cover for fuel removal, removal of large rubble from the spent fuel pool was completed in November 2015. To ensure safe and steady fuel removal, training of remote control was conducted at the factory using the actual fuel-handling machine which will be installed on site (February – December 2015). Measures to reduce dose on the Reactor Building top floor (decontamination, shields) were completed in December 2016. Installation of a cover for fuel removal and a fuel-handling machine is underway from January 2017. Installation of the fuel removal cover was completed on February 23, 2018.

Toward fuel removal, the rubble retrieval training inside the pool, which was scheduled in conjunction with fuel removal training, started from March 15, 2019, and started fuel removal from April 15, 2019.

Common pool
Storage area
An open space will be maintained in the common pool (Transfer to the temporary cask custody area)

Progress to date
- The common pool has been restored to a condition allowing it to re-accommodate fuel to be handled (November 2012)
- Loading of spent fuel stored in the common pool to dry casks commenced (June 2013)
- Fuel removal from the Unit 4 spent fuel pool began to be received (November 2013 - November 2014)
- Fuel removal from the Unit 1 spent fuel pool began to be received (from April 2019)

Temporary cask (*1) custody area
Spent fuel is accepted from the common pool

Operation commenced on April 12, 2013, from the cask storage building, transfer of 9 existing dry casks completed (May 21, 2013); fuel stored in the common pool sequentially transferred.

<Reference> Progress to date
Previously, potential to recover the existing overhead crane and the fuel handling machine was examined. However, the high radiation dose inside the operating floor meant the decision was taken to dismantle the upper part of the building in November 2015. Findings from internal investigations of the operating floor from November 2018 to February 2019 underlined the potential to conduct limited work there and the means of accessing from the south side had been examined.

Progress toward decommissioning: Works to identify the plant status and toward fuel debris retrieval

**Immediate target**
Identify the plant status and commence R&D and decontamination toward fuel debris retrieval

---

**Investigation into TIP Room of the Unit 1 Reactor Building**
- To improve the environment for future investigations inside the PCV, etc., an investigation was conducted from September 24 to October 2, 2015 at the TIP Room (1). (Due to high dose around the entrance to the TIP Room, the investigation of dose rate and contamination distribution was conducted through a hole drilled from the walkway of the Turbine Building, where the dose was low)
- The investigative results identified high dose at X-31 to 33 penetrations (instrumentation penetration) and low dose at other parts.
- As it was confirmed that work inside the TIP room would be available, the next step will include identification of obstacles which will interfere the work inside the TIP Room and formulation of a plan for dose reduction.

---

**Investigation in the leak point detected in the upper part of the Unit 1 Suppression Chamber (S/C)**

Investigation in the leak point detected in the upper part of Unit 1 S/C from May 27, 2014 from one expansion joint cover among the lines installed there. As no leakage was identified from other parts, specific methods will be examined to halt the flow of water and repair the PCV.

---

**Status of investigation inside the PCV**
Prior to fuel debris retrieval, an investigation inside the PCV will be conducted to inspect the status there including the location of fuel debris.

**[Investigative outline]**
- In April 2015, a device, which entered the inside of the PCV through a narrow access opening (bone: \( \Phi 100 \) mm), collected information such as images and airborne dose inside the PCV 1st floor.
- In March 2017, the investigation using a self-propelled investigation device, conducted to inspect the spreading of debris to the basement floor outside the pedestal, took images of the PCV bottom status for the first time. The status inside the PCV will continue to be examined based on the collected image and dose data.

---

Investigation into the Reactor Building

(1) Replacement of the RPV thermometer

- As the thermometer installed at the Unit 2 RPV bottom after the earthquake had broken in February 2014, it was excluded from the monitoring thermometers.
- In April 2014, the broken thermometer failed and was suspended. During this period, a new thermometer was installed in March. This thermometer has been used as part of permanent supervisory instrumentation since April.

(2) Reinstallation of the PCV thermometer and water-level gauge

- Some of the permanent supervisory instrumentation for PCV could not be installed in the planned locations due to interference with existing grating (August 2013). The instrumentation was removed in May 2014 and new instruments were reinstalled in June 2014. The trend of added instrumentation will be monitored for approx. one month to evaluate its validity.

- The measurement during the installation confirmed that the water level inside the PCV was approx. 300mm from the bottom.

Investigative results on torus chamber walls

- July 2014, the torus chamber walls were investigated (on the north, east-side walls) using equipment specially developed for that purpose (a swimming robot and a floor traveling robot).
- At the east-side wall pipe penetrations (five points), “the status” and “existence of flow” were checked.
- A demonstration using the above two types of underwater wall investigative equipment showed how the equipment could check the status of penetration.
- Regarding Penetrations 1 - 5, the results of checking the sprayed tracer (as) by camera showed no flow around the penetrations. (investigation by the swimming robot)
- Regarding Penetration 3, a sonar check showed no flow around the penetrations. (investigation by the floor traveling robot)

Status of investigation inside the PCV

Prior to fuel debris retrieval, an investigation inside the PCV will be conducted to inspect the status there including the location of fuel debris.

Investigative outline

- Investigative devices such as a robot will be injected from Unit 2 X-6 penetration (as) and access the inside of the pedestal using the ORD rail.

[Progress status]

- On January 26 and 30, 2017, a camera was inserted from the PCV penetration to inspect the status of the CRD replacement rafter on which the robot will travel. On February 9, the robot, which the access route of the self-propelled investigative device was removed and on February 16, the inside of the PCV was investigated using the device.
- The results of this series of investigations confirmed fallen and deformed gratings and a quantity of deposit inside the pedestal.
- On January 19, 2018, the status below the platform inside the pedestal was investigated using an investigatory tool with a hangover mechanism. From the analytical results of images obtained in the investigation, deposits probably including fuel debris were found at the bottom of the pedestal. In addition, multiple parts higher than the surrounding deposits were also detected. Obtained data were processed in panoramic image visualization to acquire clearer images.
- On February 13, 2019, an investigation touching the deposits at the bottom of the pedestal and on the platform was conducted and confirmed that the pebble-shaped deposits, etc. could be moved and that hard rock-like deposits that could not be gripped may exist.
- In addition, images, etc. would help determine the contour and size of the deposits could be collected by moving the investigation unit in the deeper deposits than the previous investigation.

Progress toward decommissioning: Works to identify the plant status and toward fuel debris retrieval

Immediate target: Identify the plant status and commence R&D and decontamination toward fuel debris retrieval

**Water flow was detected from the Main Steam Isolation Valve room**

On January 18, 2014, a flow of water from around the Steam Isolation Valve room in the Reactor Building Unit 3 1st floor northeast area to the nearby floor drain funnel (drain outlet) was detected. As the drain outlet connects with the underground part of the Reactor Building, there is no possibility of outflow from the building.

From April 23, 2014, image data has been acquired by camera and the radiation dose measured via pipes for measurement instrumentation, which connect the air-conditioning room on the Reactor Building 2nd floor with the Main Steam Isolation Valve Room on the 1st floor. On May 15, 2014, water flow from the expansion joint of one Main Steam Line was detected. This is the first leak from PCV detected in the Unit 3. Based on the images collected in this investigation, the leak volume will be estimated and the need for additional investigations will be examined. The investigative results will also be utilized to examine water stoppage and PCV repair methods.

**Investigative results into the Unit 3 PCV equipment hatch using a small investigation device**

- As part of the investigation into the PCV to facilitate fuel debris retrieval, the status around the Unit 3 PCV equipment hatch was investigated using a small self-traveling investigation device on November 26, 2015.
- Given blots such as rust identified below the water level inside the PCV, there may be a leakage from the seal to the extent of bleeding. Methods to investigate and repair the parts, including other PCV penetrations with a similar structure, will be considered.

**Investigation inside the PCV**

Prior to fuel debris retrieval, the inside of the Primary Containment Vessel (PCV) was investigated to identify the status there including the location of the fuel debris.

**[Investigative outline]**

- The status of X-3 penetration(4), which may be under the water and which is scheduled for use to investigate the inside of the PCV, was investigated using remote-controlled ultrasonic test equipment. The results showed that the penetration was not under the water (October 22-24, 2014).
- For the purpose of confirming the status inside the PCV, an investigation device was inserted into the PCV from X-3 penetration on October 20 and 22, 2015 to obtain images, data of dose and temperature and sample contaminated water. No damage was identified on the structure and walls inside the PCV and the water level was almost identical with the estimated value. In addition, the dose inside the PCV was confirmed to be lower than in other Units.
- In July 2017, the inside of the PCV was investigated using the underwater ROV (remotely operated underwater vehicle) to inspect the inside of the pedestal. Analysis of image data obtained in the investigation identified damage to multiple structures and the supposed core internals. Consideration about fuel removal based on the obtained information will continue.
- Videos obtained in the investigation were reproduced in 3D. Based on the reproduced images, the relative positions of the structures, such as the rotating platform slipping off the rail with a portion buried in deposits, were visually understood.

Secretariat of the Team for Countermeasures for Decommissioning and Contaminated Water Treatment

Progress toward decommissioning: Work related to circulation cooling and contaminated water treatment line

**Immediate target**
Stably continue reactor cooling and contaminated water treatment, and improve reliability

Work to improve the reliability of the circulation water injection cooling system and pipes to transfer contaminated water.
- Operation of the reactor water injection system using Unit 3 Condensate Storage Tank (CST) as a water source commenced (from July 5, 2013). Compared to the previous systems, the reliability of the reactor water injection system was enhanced, e.g. by increasing the amount of water-source storage and enhancing durability.
- To reduce the risk of contamination from leakage, the circulation loop was shortened by installing a reverse osmosis (RO) device in the Unit 4 Turbine Building within the circulation loop, comprising the transfer of contaminated water, water treatment and injection into the reactors. Operation of the installed RO device started from October 7 and 24-hour operation started from October 20. Installation of the new RO device inside the building shortened the circulation loop from approx. 3 to 0.8 km.
- To accelerate efforts to reduce the radiation density in contaminated water inside the buildings, circulating purification of contaminated water inside the buildings started in July 2013, in H5 and H5 north areas (31 tanks) in June 2018, in G6 area (38 tanks) in July 2018, H6 and H6 north areas (24 tanks) in September 2018 and G4 south area (17 tanks) in March 2019.
- To reduce the risk of contaminated water leakage, the circulation loop was shortened by installing a reverse osmosis (RO) device in the Unit 4 Turbine Building within the circulation loop, comprising the transfer of contaminated water, water treatment and injection into the reactors. Operation of the installed RO device started from October 7, 2013. Installation of the new RO device inside the building shortened the circulation loop from approx. 3 to 0.8 km.
- The risks of contaminated water inside the buildings will continue to be reduced in addition to reduction of its storage.

**Progress status of dismantling of flange tanks**
- To facilitate replacement of flanged tanks, dismantling of flanged tanks started in H1 east/H2 areas in May 2015. Dismantling of all flanged tanks was completed in H1 east area (12 tanks) in October 2015, in H2 area (28 tanks) in March 2016, in H4 area (56 tanks) in May 2017, in H3 B area (31 tanks) in September 2017, in H5 and H5 north areas (31 tanks) in June 2018, in G6 area (38 tanks) in July 2018, H6 and H6 north areas (24 tanks) in September 2018 and G4 south area (17 tanks) in March 2019.
- To reduce the risk of contaminated water leakage, the circulation loop was shortened by installing a reverse osmosis (RO) device in the Unit 4 Turbine Building within the circulation loop, comprising the transfer of contaminated water, water treatment and injection into the reactors. Operation of the installed RO device started from October 7, 2013. Installation of the new RO device inside the building shortened the circulation loop from approx. 3 to 0.8 km.
- The risks of contaminated water inside the buildings will continue to be reduced in addition to reduction of its storage.

**Completion of purification of contaminated water (RO concentrated salt water)**
Contaminated water (RO concentrated salt water) is being treated using seven types of equipment including the multi-nuclide removal equipment (ALPS). Treatment of the RO concentrated salt water was completed on May 27, 2015, with the exception of the remaining water at the tank bottom. The remaining water will be treated sequentially onward dismantling the tanks.

**Preventing groundwater from flowing into the Reactor Buildings**
Reducing groundwater inflow by pumping sub-drain water
To reduce groundwater flowing into the buildings, pumping-up of groundwater from wells (sub-drains) around the buildings started on September 3, 2015. Pumped-up groundwater was purified at dedicated facilities and released after TEPCO and a third-party organization confirmed that its quality met operational targets.

Via a groundwater bypass, reduce the groundwater level around the Building and groundwater inflow into the Building.
Measures to pump up groundwater flowing from the mountain side upstream of the Building to reduce the groundwater inflow (groundwater bypass) have been implemented.

The pumped-up groundwater is temporarily stored in tanks and released after TEPCO and a third-party organization confirmed that its quality meets operational targets.

Through periodical monitoring, pumping of wells and tanks is operated appropriately. At the observation holes installed at a height equivalent to the buildings, the trend showing a decline in groundwater levels is checked.

The analytical results on groundwater inflow into the buildings based on existing data showed a declining trend.

Installing land-side impermeable walls with frozen soil around Units 1-4 to prevent the inflow of groundwater into the building
To prevent the inflow of groundwater into the buildings, installation of impermeable walls on the land side is planned. Freezing started on the sea side and as a part of the mountain side, focusing on the mountain side from March 2016 and at 95% of the mountain side from June 2016. Freezing of the remaining unfronged sections advanced with a phased approach and freezing of all sections started in August 2017.

In March 2018, construction of the land-side impermeable walls was completed, except for a portion of the depth, based on a monitoring report that the underground temperature had declined below 0°C in almost all areas, while on the mountain side, the difference between the inside and outside increased to approx. 4.5 m. The 21st Committee on Countermeasures for Contaminated Water Treatment, held on March 7, 2016, evaluated that together with the function of sub-drains, etc., a water-level management system to stably control groundwater and isolate the buildings from it had been established and had allowed a significant reduction in the amount of contaminated water generated.

For the unfrozen depth, a supplementary method was implemented and it was confirmed that temperature of the part declined below 0°C by September 2018. From February 2019, maintenance operation started at all sections.

Progress toward decommissioning: Work to improve the environment within the site

Immediate targets

- Reduce the effect of additional release from the entire power station and radiation from radioactive waste (secondary water treatment waste, rubble, etc.) generated after the accident, to limit the effective radiation dose to below 1mSv/year at the site boundaries.
- Prevent contamination expansion in sea, decontamination within the site

Optimization of radioactive protective equipment

Based on the progress of measures to reduce environmental dosage on site, the site is categorized into two zones: highly contaminated area around Unit 1-4 buildings, etc. and other areas to optimize protective equipment according to each category aiming at improving safety and productivity by reducing load during work. From March and September 2017, the G Zone was expanded.

Installation of dose-rate monitors

To help workers in the Fukushima Daiichi Nuclear Power Station precisely understand the conditions of their workplaces, a total of 86 dose-rate monitors were installed by January 4, 2016. These monitors allow workers to confirm real time on-site dose rates at their workplaces. Workers are also able to check concentrated data through large-scale displays installed in the Main Anti-Earthquake Building and the access control facility.

Installation of sea-side impermeable walls

To prevent the outflow of contaminated water into the sea, sea-side impermeable walls have been installed. Following the completed installation of steel pipe sheet piles on September 22, 2015, connection of these piles was conducted and connection of sea-side impermeable walls was completed on October 26, 2015. Through these works, closure of sea-side impermeable walls was finished and the contaminated water countermeasures have been greatly advanced.

Status of the large rest house

A large rest house for workers was established and its operation commenced on May 31, 2015. Spaces in the large rest house are also installed for office work and collective worker safety checks as well as taking rest.

On March 1, 2016 a convenience store opened in the large rest house, operation of the shower room started. Efforts will continue to improve convenience of workers.
